Guidance for Water Utilities on Managing the Implementation of Residential Fire Sprinkler Systems in Community Water Systems

**Project Team**

Gary Trachtman, Arcadis
George Kunkel, Kunkel Water Efficiency Consulting
Steve Davis, Metering Technology Consultants
Allan Morris, Arcadis

**Project Advisory Committee**

Neil Kaufman, Truckee Donner Public Utility Dist.
Roland Asp, National Fire Sprinkler Association
Juneseok Lee, San Jose State University
Peter Mayer, Water Demand Management
Kathlie Bulloch, City of Houston, TX
Travis Smith, Sensus, a Xylem Brand
Jim Siriano, AWWA Staff
Purpose: provide water utilities with information on residential fire sprinkler systems (RFSS) and guide them in setting their own policies and procedures for the design, installation, and operation of their water distribution system supporting RFSS use.

Google “AWWA Fire Sprinkler Report”

https://www.awwa.org/AWWA-Articles/managing-the-growing-use-of-residential-fire-sprinkler-systems
Fire Protection History: a Public or Private Service?

- Benjamin Franklin founded the Union Fire Company in Philadelphia in 1736
- Many fire companies existed and aligned with insurance companies; giving preference for fire extinguishing to subscribers of the insurance company
- The “fire mark” was mounted to the building so fire fighters would know who subscribed to the insurance company

Water was carried by hand from supplies from private wells or from Philadelphia’s two major rivers
Community Water Systems and Fire Protection

- Needed to protect against great conflagrations
- Water inundation: primary form of fire suppression; water systems were designed with fire flow capacity

First Fire Sprinkler Systems

- First automatic sprinkler system: Phillip Pratt, 1870’s
- Standard design by Henry Parmalee and Frederick Grinnell by the 1890’s.

For many years fire sprinklers existed primarily in industrial, commercial and multi-family buildings
Fire Protection in the Residential Sector

- “Residential” is the leading property type for fire deaths, fire injuries, and fire dollar loss.

**Average annual fire statistics of:**

- 2,510 civilian fire deaths, or 93% of all civilian structure fire deaths,
- 12,300 civilian fire injuries, or 87% of all civilian structure fire injuries, and
- $6.7 billion in direct damage, or 68% of total direct damage in structure fires.
## Disposition of Residential Fire Sprinklers by US State

| National Fire Protection Association—Fire Sprinkler Initiative | States prohibiting statewide and new, local adoptions of fire sprinkler requirements (31) *

- Promoting RFSS: fire safety and protection community
- Challenging RFSS: home building community
Scottsdale, AZ
the Longest Running RFSS Community in the USA

- Over 50,000 residential buildings are now sprinklered
- Only one fire death in RFSS property in +30 years (Over one dozen deaths in non-RFSS buildings)
- Registered $2,166 average property loss per fire incident in sprinklered properties, compared to $45,000 average loss per non-sprinkled building fire
- Property damage of $7.31 per capita vs. $27 per capita for US properties
- Fire hydrant spacing increased from 660 feet to 1,200 feet
- Removed requirement for 360-degree access to allow more developed property. Increased building development density by 4%
RFSS Guidance to Water Utilities:

- Codes, Manuals, Standards
- Service Line configuration and sizing
- Metering
- Water quality assurance
- Permitting
- Water Rates and Charges

Stakeholder Coordination is Key! Water utility, fire, code, fire system designers, customers, elected officials, media, insurers

AWWA Policy Statement on Residential Fire Sprinklers

Residential Fire Sprinklers

AWWA recognizes the increasing use of residential fire sprinkler systems and recommends that they be designed, by licensed or accredited professionals; approved by the appropriate local agencies (water utility, fire department and/or other approval agency) to ensure adequate flow, pressure, and backflow protection; and installed by licensed fire sprinkler contractors or properly trained personnel.

International Codes: International Code Council (ICC) adopted amendment to 2009 International Residential Code (IRC), mandating all new 1- and 2-family residential dwellings be equipped with RFSS. The International Fire Code (IFC) also requires sprinkler protection for all residential occupancies.

Uniform Construction Codes within the USA: CA, MD and DC maintain a uniform construction code based upon the IRC and have a RFSS requirement.

Individual Jurisdictions within the USA: Many individual jurisdictions (cities, towns, municipalities) have adopted local RFSS ordinances. But a majority of states prohibit local jurisdictions from adopting RFSS ordinances. NY, MA have RFSS requirements for certain buildings.
National Fire Protection Association (NFPA) Sprinkler System Design Standards

NFPA 13 Standard: *Standard for the Installation of Sprinkler Systems*. Life safety and protection to the facility and assets. Fire protection throughout the entire building, including unoccupied spaces.

NFPA 13D Standard: *Standard for the Installation of Sprinkler Systems in One- and Two-Family Dwellings and Manufactured Homes*. Minimum requirements standard to provide *life safety protection, not property protection*. Certain building spaces can go un-sprinklered. Needed water discharge is least of all standards: 13 gpm per sprinkler head; available for min 7-10 minutes at a minimum of 7 psi.

NFPA also publishes several other codes that comment on fire sprinkler use.
NFPA 13D Standard – Distinction Among the 3 Standards

- Annual sprinkler system certification is **not** required
- Audible alarm is **not** required (if home is equipped with smoke detectors)
- Occurs as separate fire and domestic lines in some jurisdictions, or as a single line supplying both fire and domestic flows in others (NFPA 13 and 13R systems are always separate lines)
- Backflow protection typically need **not** be required on domestic lines and lines supplying both fire and domestic flow, particularly those with a passive purge (fire line connection to a toilet tank) configuration.
- Backflow protection of separate fire lines is **typically** required

*In the NFPA 13D environment for RFSS, a burden falls upon the homeowner to ensure systems (fire, backflow protection) are in working order. Annual system inspections and fees may be required.*
Manual M31 – *Distribution System Requirements for Fire Protection*: guidance on traditional water utility fire protection, and a chapter on RFSS.

Manual M22 – *Sizing Water Service Lines and Meters*: guidance on determining expected water demands in customer buildings that are used to properly size and specify water service lines and water meters. Brief discussion on RFSS.

Manual M14 - *Recommended Practice for Backflow Prevention and Cross Connection Control*: information on backflow prevention, with recommended backflow prevention practice for residential, one- and two-family dwelling fire protection systems. Defines different levels of building hazards that may exist.

AWWA Guidance for Water Meters in the RFSS Environment

AWWA Standard C714-13 – *Cold-Water Meters for Residential Fire Sprinkler Systems in One- and Two-Family Dwellings and Manufactured Homes*: sets minimum manufacturing and performance requirements for water meters used for RFSS. Not prescriptive in defining the use of water meters on fire supply lines.

Note: The fire protection community prefers no meter on the fire sprinkler supply line.

**It is up to the utility to determine:**

1. if a water meter is required on the fire supply line
2. the specific features and specifications of the water meter.
Consider requiring an affidavit be provided by the meter manufacturer confirming that their water meter will continue to deliver water under a “locked measuring element” condition.

The NFPA 13D Standard does not require that water meters used in RFSS applications be listed under the provisions of Underwriters Laboratories, Inc. (UL), Factory Mutual Company (FM), or other insurance underwriting agency. This is a utility-specific decision.

Per NFPA 13D and AWWA M22, standard water meters used in domestic water supply applications are acceptable for use in RFSS applications. It is up to the water utility to require, or not require, that any of the provisions of the AWWA C714-13 be used.

Some recent research suggests that water meters can sustain a brief period of flow higher than the rated max

### Flowrate limits of the recommended flow ranges of positive displacement meters*

*Gathered from standard manufacturer product literature (solid state meters are also used in RFSS applications)
Historically for Water Utilities:

- **Domestic water supply** – separately tapped line from the water main supplying domestic use fixtures in the building with distinct rates/charges
- **Fire supply** – larger connections that are separately tapped and supply fire sprinkler heads usually with a fixed, or standby, charge

Now:

- **RFSS** – can be a “hybrid” of the above two conditions – this challenges existing policy structures for many utilities
Stand-alone – dedicated fire line to sprinkler heads

Three options include a single tapping into the water main for a line that provides both domestic and fire supply.

A fourth option features separate lines: one for domestic service and one for fire

Source: NFPA 13D Standard
Multi-purpose Service Line Configurations

**Multi-purpose** – simultaneously supplies both domestic fixtures and fire sprinkler heads from the same piping.

The multipurpose configuration has an advantage of better maintaining water quality by avoiding stagnation.

**Tree** – domestic supply lines branch off of single primary supply line from water main. The primary supply extends into the building to supply sprinkler heads from dead-ended branch piping off of the primary supply pipe.

**Looped** – domestic supply lines branch off of single primary supply line from water main. The primary supply extends into the building and forms a loop of piping that supplies sprinkler heads.

**Network** – a unique design where each sprinkler head can be supplied water from a minimum of three different paths. (Now uncommon because the fittings needed to establish three paths to sprinklers are no longer being manufactured.)

**Passive purge:** includes piping that serves a single, remote toilet in addition to the fire sprinklers.
Maintaining Water Quality

Water quality can deteriorate in stagnant fire lines

Two controls can be considered:

1) select a piping configuration that minimizes the stagnation of water: multi-purpose, passive purge

2) provide acceptable backflow protection if the piping configuration results in stagnant water
   - Need to factor backflow installation/maintenance into the decision
   - Hundreds of thousands of backflow devices will exist in the residential sector, and must be maintained by homeowners

This is a foremost and highly important consideration in the RFSS design
Service Discontinuance

• In typical RFSS designs, halting water service also halts supply to the RFSS. This can be acceptable because:
  ‒ Most buildings need water service to maintain the Certificate of Occupancy. Buildings with discontinued water service should be vacated.
  ‒ RFSS exist for life safety; these systems are not required to function in unoccupied buildings.
• Realistically, discontinuance to fire lines generates concern with fire/code officials.
• Be proactive in coordinating service discontinuance policy with fire/code officials

AWWA Policy Statement

**Discontinuance of Water Service for Nonpayment**

AWWA realizes the importance of the nondiscriminatory billing and collection procedures to ensure that each customer pays for the services rendered by the utility under its rates and tariffs. Failure on the part of the customer to pay a water bill necessitates that other customers bear the burden of paying for the service.

AWWA recognizes that certain circumstances may require some flexibility because water service is a necessity in maintaining sanitary conditions in the home and may be required for life-sustaining equipment. It may also be a vital part of industrial and commercial operations. Discontinuance of water service for nonpayment is considered a final phase of a collection procedure and should be instituted with sufficient notification when all other reasonable alternatives have been exhausted.

Hydraulic Requirements and Line Sizing

- NFPA 13D: minimum operating pressure of 7 psi at sprinkler heads. Sprinkler designers should obtain the static pressure from the utility water distribution system.

- Typical demand per sprinkler is 13 gpm. Design assumes 2 sprinklers activated simultaneously. **Typical max flow is 26-35 gpm.** For homes with landscape irrigation, max flow may be up to 40 gpm.

- NFPA 13D: min water main size of 4-inch diameter. Service line size depends on the specified flowrate, available pressure, & expected head loss, but must be at least ¾-inch diameter.
Piping Materials

- Copper - Traditional
- CPVC – common with RFSS (Chlorinated Polyvinyl Chloride)
- PEX – very common with RFSS (Cross-linked Polyethylene)

PEX in manifold

Typical Stand-alone configuration
Rates and Charges

Established a intermediate fixed rate for RFSS

Considerations include:

- Connection charges
- Meter sizing costs
- Fixed charges – often based upon meter size, may take into account sewer/other charges also
- Other charges

Concern: RFSS may be a “hybrid” and need a new class of service in your rate structure.
Coordination is Key

The Implementation of RFSS impacts multiple stakeholders:

- **Water utility staff**
- **Fire Departments**
- **Code Officials**
- **Fire Protection System Designers & Installers**
- **Contractors: Builders, Plumbing**
- **Customers**
- **Insurers**
- **Elected officials**
- **Media**
